

Note: this should work on any hypervisor/linux distro, but it was built and tested using VMWare/Kali, so the instructions will be based off of those.

- Install VMWare.
 - Download the installer [here](#).
 - You will need to make an account and sign in with it.
 - For me, when I signed in it brought me to the dashboard. Just click the link again to the download page.
 - Download the installer for your OS and install it.
- Download the pre-built Kali image from [Kali's official site](#)
- Open VMWare and go to File -> Open -> navigate to where you extracted the zip -> select the .vmx file.
- Go to "Edit virtual machine settings" and then "Options" to change the name of the VM. You can also optionally change the memory/CPU allocation if you want. I changed the RAM from 2 GB to 8 and left the cores at 4.
- Power on the VM. The default login credentials should be "kali" for the username and password.
 - Note: When I was first messing with this, I noticed my files weren't saving across reboots. Making a snapshot seemed to fix it, but when running through the setup again with a fresh download of the image, the files seemed to save without needing to do this. So before you do anything, I would create a test file, reboot, and check to see if it saved.
- Clone the repo into any directory of your choosing.
 - **cd [directory to clone into]**
 - **git clone https://github.com/infrastructure-hacking-platform/GamifiedICS**
- Once that's done, run **cd GamifiedICS/Backend/GamifiedICS**.
 - If it says "cd: no such file or directory: GamifiedICS/Backend/GamifiedICS", make sure your current working directory is the same one you cloned into.
- Now run the following 3 commands:
 - **sudo chmod +x setup.sh**
 - You will be prompted for the password, again it should be "kali".
 - **dos2unix setup.sh**
 - **./setup.sh**
 - This will run the startup script and do the rest. It will take some time.
